

Student Record Management System Using Singly Linked List

➤ Problem Statement

Managing student records manually in notebooks or files can be time-consuming and may lead to data duplication, loss, and difficulty in updating or searching records. As the number of students increases, maintaining accurate records and accessing specific information such as roll number, name, branch, and marks becomes more difficult. Therefore, there is a need for a simple and efficient Student Record Management System that can store and manage student information dynamically. This project uses a Singly Linked List in C++ to provide operations such as adding new student records, displaying all records, searching for a student, updating student information, and deleting records when required. The system helps demonstrate how linked lists can be practically used for dynamic data management and makes student record handling more organized, flexible, and efficient.
